The Logistic Model of Population Growth

In applications we often have info about the rate of change of a quantity
Eg. Consider a population of organisms, $P(t)$, with unlimited resources (space, food, etc)

That is, $\frac{dP}{dt} = aP$ for some $a \in \mathbb{R}$

$$\rightarrow P(t) = Ce^{at}$$

At $t = 0$ we have $P(0) = C$, so C is the initial population.

$$P(t) = P_0 e^{at}$$

(this is the Malthusian model of population growth)

Malthus suggested including a "carrying capacity", K (a maximum sustainable population). How might we modify the equation?

One way: The Logistic Model

We should alter it in such a way that the derivative is 0 when we reach K

$$\frac{dP}{dt} = aP\left(1 - \frac{P}{K}\right)$$

Now Jan 18th:

Summary from last day:

$$\frac{dP}{dt} = aP\left(1 - \frac{P}{K}\right)$$

where a is a proportionality constant, and K is the carrying capacity

(Note that $\frac{dP}{dt} \approx aP$ when $P \ll K$ and $\frac{dP}{dt} \approx 0$ when $P \approx K$)

Solution?

$$\begin{aligned} \int \frac{dP}{P(1 - \frac{P}{K})} &= \int a dt \\ \int \frac{dP}{P(1 - \frac{P}{K})} &= \int \frac{K}{P(K - P)} dP = \dots \end{aligned}$$

we find:

$$P(t) = \frac{k}{Ce^{-at} + 1}$$

$$P(0) = P_0 \rightarrow P(t) = \frac{kP_0}{(k - P_0)e^{-at} + P_0}$$

DE's Arising from Physical Laws

Newton's 2nd law of motion

For relatively small velocities ($v \ll c \approx 3 \times 10^8 \text{m/s}$) this states that $\frac{d}{dt}(mv) = F$. m = mass, v = speed, F = net force

If m is constant we have $m \frac{dv}{dt} = F$, ie $F = ma$

Since $V = \frac{dx}{dt}$ (if x is displacement! we may also write $m \frac{d^2x}{dt^2} = F$
(See fig5.1)

Example: The sky diver problem:

This is in the course notes, but we are setting it up slightly different.

An object of mass m , in free fall is subject to forces of gravity and air resistance (drag).

I will treat (slightly different than course notes) "up" will be the positive direction so $x(t)$ is height above the ground.

Let $v(t) = \frac{dx}{dt}$

Consider the forces:

Gravity: $F_g = -mg$ ($g \approx 9.8 \text{m/s}^2$)

Air Resistance: Complicated. We will simply assume $F_{air} = -\alpha v$

Combining these, $F = F_g + F_{air} = -mg - \alpha v$

$\rightarrow m \frac{dv}{dt} = -mg - \alpha v$

ie $\frac{dv}{dt} + \frac{\alpha}{m}v = -g$

We have $V_c = Ce^{\frac{-\alpha}{m}t}$

For V_p ? Try $V = A$, we guess a constant (A zero'th order polynomial) then

$v' = 0$

so $\frac{\alpha}{m}A = -g$

So $A = \frac{-mg}{\alpha}$

Thus, $v(t) = Ce^{\frac{-\alpha}{m}t} - \frac{mg}{\alpha}$

If the object was dropped from rest, then $v(0) = 0$, and so $0 = C - \frac{mg}{\alpha}$, so $C = \frac{mg}{\alpha}$, and so $v(t) = \frac{mg}{\alpha}(e^{\frac{-\alpha}{m}t} - 1)$
(see Fig5.2)

Circuit Analysis

A simple circuit containing a resistor and a capacitor may be illustrated like this: (fig 5.3). Here, $V(t)$ is a source voltage (could be constant for a battery, eg) and $i(t)$ is the current. R is the resistance (in ohms) of a resistor and C is the capacitance (in Farads) of a capacitor.

We have a set of def's/experimental laws which govern these circuits:

Kirchhoff's Voltage Law:

$$v(t) = V_R(t) + V_C(t)$$

V_R and V_C are the voltage drops (losses of potential energy) at RPC

Ohm's law:

$$V_R(t) = iR$$

Definition of C

$$V_C(t) = \frac{1}{C}q$$

where $q(t)$ is the charge at the capacitor

$$q(t) = \int_0^t i(t)dt$$

ie $i(t) = \frac{dq}{dt}$

From Jan 20th:

Combining these:

$$\begin{aligned} V &= V_R + V_C \\ &= Ri(t) \end{aligned}$$

$$\rightarrow V = R \frac{dq}{dt} + \frac{q}{C}$$

That is:

$$\frac{dq}{dt} + \frac{q}{RC} = \frac{V}{R}$$

(A first order linear DE for the charge on the capacitor!)

Let's assume V is constant (the source voltage is a battery).

The solution to the homogeneous:

$$q_h = K e^{-\frac{t}{RC}}$$

A particular solution:

We try $q = A$ Then $q' = 0$, so we have $0 + \frac{A}{RC} = \frac{V}{R}$ so $A = VC$

$$\rightarrow q(t) = K e^{-\frac{t}{RC}} + VC$$

If $q(0) = 0$ then $0 = K + VC$ so $K = -VC$

and so $q(t) = VC[1 - e^{-\frac{t}{RC}}]$

See Fig5.4

Therefore $i(t) = \frac{dq}{dt} = \frac{V}{R} e^{-\frac{t}{RC}}$

See Fig5.5

Also $V_R(t) = V e^{-\frac{t}{RC}}$ and $V_C(t) = V[1 - e^{-\frac{t}{RC}}]$
